The enigmatic chronic fatigue syndrome: cellular and molecular pathogenesis. The etiology and pathogenesis of chronic fatigue syndrome (CFS) are highly controversial. Because of its heterogeneous features, it is difficult to use a "model" disease for CFS. Recent advances in our understanding of the cellular and molecular mechanisms of infection by human immunodeficiency virus (HIV) have served as a model for the pathogenesis of CFS. Although not all CFS patients are infected with HIV, CFS-like syndrome has been described in patients infected with HIV and in those who are immune competent. CFS-like symptoms can be induced or exacerbated by microbial agents associated with HIV infection and, therefore, direct HIV infection of CD4 cells may play a role in the pathogenesis of CFS. We have identified a metabolic profile of HIV-infected cells that is closely correlated with the CFS-like syndrome. This correlation is supported by the normalization of the metabolic profile with the administration of the anti-HIV drug AZT.
